## Data input

### S1: Historical data

Table S1 reported all historical data used in the Colo-Sim. We used data from Thai database to represent colorectal cancer (CRC) care in Thailand. We also used data from UN database and projections as external data to capture the aging trend in Thailand. (See raw data of historical data the online data repository.)

However, historical data on the prevalence and CRC deaths are limited. Thus, we estimated them using data from literature and assumptions. We estimated the initial prevalence of CRC in each stage using calibration. We used the most extensive survival analysis of CRC to represent the crude death rate of symptomatic diagnosed CRC. For undiagnosed and asymptomatic diagnosed CRC, we estimated the crude death rate from the following formulation.

For  $\forall X \in \{1,2,3,4\}$ ,

$$\begin{aligned} & \text{crude death rate of undiagnosed and asymptomatic diagnosed CRC stage } X \\ &= \text{crude death rate of symptomatic diagnosed CRC stage } X \\ & * \text{crude death rate ratio in undiagnosed and asymptomatic diagnosed CRC} \end{aligned}$$

**Table S1.** Source of historical data and projections

Variable	Unit	Source
Annual deaths in population 49 years old	People/year	[1]
Annual deaths in population 50 years old or more	People/year	[1]
Annual deaths in population 75 years old or more	People/year	[1]
Colonoscopy for FIT screening per year	People/year	[2]
CRC detected by FIT screening per year	People/year	[2]
CRC stage 1 detected by symptom per year	People/year	[2–22]
CRC stage 2 detected by symptom per year	People/year	[2–22]
CRC stage 3 detected by symptom per year	People/year	[2–22]
CRC stage 4 detected by symptom per year	People/year	[2–22]
FIT participation per year	People/year	[2]
FIT positive per year	People/year	[2]
Normal results in colonoscopy from FIT screening per year	People/year	[2]
Polyp detected by FIT screening per year	People/year	[2]
Population 49 years old	People	[1]
Population 50 years old or more	People	[1]
Population 75 years old or more	People	[1]

## S2: Model parameters

**Table S2.** Model parameters

Variable	Value	Unit	Source
Accessibility to FIT ratio in population without tumors	1.17	Dmnl	Calibration
Average time in FIT positive waiting for a colonoscopy	1	Year	Assumption
Colonoscopy capacity	200,000	People/year	
Crude death rate of high-risk polyp (HRP)	0.017	Per year	Calibration
Crude death rate of low-risk polyp (LRP)	0.017	Per year	
Crude death rate of population without tumors	0.017	Per year	
Crude death rate of symptomatic diagnosed CRC stage 1	0.05	Per year	
Crude death rate of symptomatic diagnosed CRC stage 2	0.08	Per year	[23]
Crude death rate of symptomatic diagnosed CRC stage 3	0.18	Per year	[23]
Crude death rate of symptomatic diagnosed CRC stage 4	0.4	Per year	[23]
Crude death rate ratio in undiagnosed and asymptomatic diagnosed CRC	0.47	Dmnl	Calibration
Initial fraction undiagnosed CRC stage 1	0.003	Dmnl	
Initial fraction undiagnosed CRC stage 2	0.0004	Dmnl	
Initial fraction undiagnosed CRC stage 3	0.0007	Dmnl	
Initial fraction undiagnosed CRC stage 4	0.0003	Dmnl	
Initial fraction undiagnosed HRP	0.0137	Dmnl	
Initial fraction undiagnosed LRP	0.1419	Dmnl	
Progression rate from CRC stage 1 to CRC stage 2	0.3	Per year	[24]
Progression rate from CRC stage 2 to CRC stage 3	0.45	Per year	[24]
Progression rate from CRC stage 3 to CRC stage 4	0.5	Per year	[24]
Progression rate from HRP to CRC stage 1	0.05	Per year	[24]
Progression rate from LRP to HRP	0.015	Per year	[24]
Progression rate from population without tumor to LRP	0.015	Per year	Calibration
Rate of coming back to observed FIT positive	0.01	Per year	Assumption
Sensitivity of colonoscopy in CRC	0.95	Dmnl	[25]
Sensitivity of colonoscopy in HRP	0.85	Dmnl	[25]
Sensitivity of colonoscopy in LRP	0.75	Dmnl	[25]
Sensitivity of FIT in CRC	0.67	Dmnl	[26]
Sensitivity of FIT in HRP	0.24	Dmnl	[27]
Sensitivity of FIT in LRP	0.076	Dmnl	[27]
Specificity of FIT	0.95	Dmnl	[26]
Symptomatic detected rate CRC stage 1	0.006	Per year	Calibration
Symptomatic detected rate CRC stage 2	0.088	Per year	
Symptomatic detected rate CRC stage 3	0.344	Per year	
Symptomatic detected rate CRC stage 4	0.657	Per year	

**Table S3.** Initial value of health states in 2004

Variable	Initial value in 2004	Unit	Source
Diagnosed screened population without tumors	0	People	Assumption
Diagnosed via symptom CRC stage 1	0	People	
Diagnosed via symptom CRC stage 2	0	People	
Diagnosed via symptom CRC stage 3	0	People	
Diagnosed via symptom CRC stage 4	0	People	
FIT false positive population without tumors	0	People	
FIT true positive CRC stage 1	0	People	
FIT true positive CRC stage 2	0	People	
FIT true positive CRC stage 3	0	People	
FIT true positive CRC stage 4	0	People	
FIT true positive HRP	0	People	
FIT true positive LRP	0	People	
Lost FIT false positive population without tumor	0	People	

Variable	Initial value in 2004	Unit	Source
Lost FIT true positive CRC stage 1	0	People	Calibration
Lost FIT true positive CRC stage 2	0	People	
Lost FIT true positive CRC stage 3	0	People	
Lost FIT true positive CRC stage 4	0	People	
Lost FIT true positive HRP	0	People	
Lost FIT true positive LRP	0	People	
Post-diagnostic colonoscopy CRC stage 1	0	People	
Post-diagnostic colonoscopy CRC stage 2	0	People	
Post-diagnostic colonoscopy CRC stage 3	0	People	
Post-diagnostic colonoscopy CRC stage 4	0	People	
Post-diagnostic colonoscopy HRP	0	People	
Post-diagnostic colonoscopy LRP	0	People	
Symptomatic Post-diagnostic colonoscopy CRC stage 1	0	People	
Symptomatic Post-diagnostic colonoscopy CRC stage 2	0	People	
Symptomatic Post-diagnostic colonoscopy CRC stage 3	0	People	
Symptomatic Post-diagnostic colonoscopy CRC stage 4	0	People	
Undiagnosed population without tumors	10,926,453	People	
Undiagnosed CRC stage 1	43,942	People	
Undiagnosed CRC stage 2	5,404	People	
Undiagnosed CRC stage 3	9,514	People	
Undiagnosed CRC stage 4	4,389	People	
Undiagnosed HRP	254,154	People	
Undiagnosed LRP	2,622,971	People	

## Model development

### S3: Surveillance colonoscopy

We estimated the number of surveillance colonoscopies based on National Comprehensive Cancer Network Guidelines® Version 3.2022 Colorectal Cancer Screening. The guideline suggested that patients with a history of a polyp or CRC should get a surveillance colonoscopy. The interval of surveillance colonoscopy depends on various factors, such as the number and grade of polyps found from the latest colonoscopy, type of cancer (colon/rectal cancer), Carcinoembryonic Antigen (CEA) level, preoperative management [28]. Due to those complexities, we simplify it based on staging at first diagnosis and the life expectancy of each stage. Table S4 reported life expectancy after diagnosis of CRC in each stage in Thailand.

**Table S4.** Life expectancy of CRC after diagnosis in Thailand

Life expectancy	Value*	Unit	Source
CRC stage 1	27.55	Year	[29]
CRC stage 2	20.05	Year	
CRC stage 3	15.2	Year	
CRC stage 4	2.15	Year	

\* Estimated from the weighted average of life expectancy between males and females in Thailand

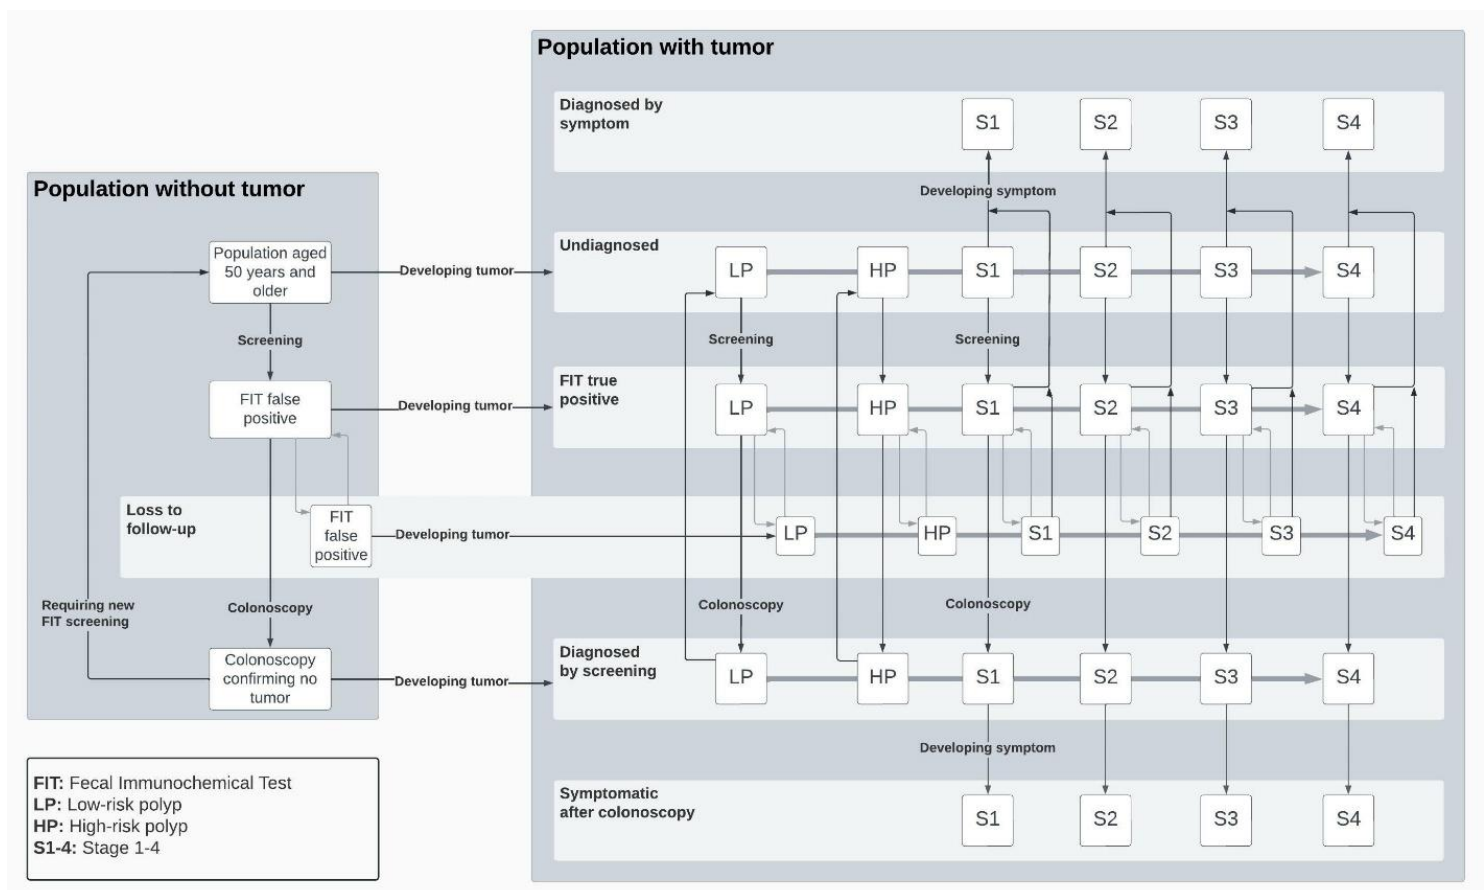

**Table S5.** Guideline for surveillance colonoscopy for CRC in each stage

Staging at first diagnosis	Guideline for surveillance colonoscopy	Source
Normal colonoscopy	No need to get surveillance colonoscopy. They need FIT screening after 10 years.	[28,30]
Low-risk polyp		
High-risk polyp	Repeat colonoscopy 3, 8 years after diagnosis.	
CRC stage 1	Repeat colonoscopy 1, 4 years after diagnosis. Then every 5 years	
CRC stage 2		
CRC stage 3		
CRC stage 4		

## Model output

### S4: Model visualization

The model used CRC disease progression based on the adenoma-carcinoma sequence. Population without tumors can generate tumors by the transition to low-risk polyp, high-risk polyp, CRC stage 1-4, respectively. We presented the overview of the Colo-Sim below.

**Fig. S1.** Overview of the Colo-Sim model

### S5: Calibration

We performed calibration using nine sets of historical data from S1 (others were used as external data) to optimize 14 unknown parameters in S2. We used mean absolute percentage error

calculated from historical data and model output by the Powell optimization method. We replicated historical data as follows.

**Fig. S2.** Graphs compared between model projection (blue lines) and historical data from Thailand (red lines)

### S6: Baseline projection

In 2022, projected FIT accessibility and accessibility to diagnostic colonoscopy are 3% and 10%, respectively. For all stages of CRC, the mean sojourn time is estimated as nine years in Thailand compared to five years in the USA [31,32]. Also, only 30% of CRC are diagnosed.

After calibrating the model with the historical data, we projected all outcomes to 2022. We estimated accessibility to FIT and diagnostic colonoscopy from the formulation below.

$$\text{accessibility to FIT} = \frac{\text{number of FIT screening per year}}{\text{undiagnosed population in 50 – 75 years old}}$$

$$\text{accessibility to diagnostic colonoscopy} = \frac{\text{number of diagnostic colonoscopy after FIT}}{\text{FIT positive population}}$$

We cannot directly quantify accessibility to symptom evaluation (AS). So, we estimated accessibility to symptom evaluation (relative to the baseline) (ASR) from the formulation below. Denote symptomatic detection rate (SDR). For  $\forall X \in \{1,2,3,4\}$ ,

$$ASR_{new} = \frac{AS_{new}}{AS_{baseline}} = \frac{SDR \text{ CRC stage } X_{new}}{SDR \text{ CRC stage } X_{baseline}}$$

$$SDR \text{ CRC stage } X = \frac{\text{CRC stage } X \text{ diagnosed by symptom per year}}{\text{Undiagnosed CRC stage } X}$$

In the main baseline assumption, we assumed that access to screening (i.e., accessibility to FIT, and accessibility to diagnostic colonoscopy) and access to symptom evaluation are projected as constants to their values in 2022. We also considered the alternative baseline of gradual increase in those access by multiplying them with 1.1 each year. Fig. S3 showed the historical and projected results of access to screening (i.e., accessibility to FIT, accessibility to diagnostic colonoscopy) and ASR in the main and alternative baseline assumptions.

**Fig. S3.** Historical data and projections of access to screening and symptom evaluation in the main (blue lines) and alternative baseline assumptions (red dot lines)

Fig. S4 showed projections of the main outcomes in both baseline assumptions. The results are largely consistent. Fig. S5-Fig. S6 compare the colonoscopy capacity, availability of diagnostic colonoscopy, and people with FIT positive per year (demands for diagnostic colonoscopy per year) in the main baseline and alternative baseline assumptions, respectively.

**Fig. S4.** Projected outcomes normalized for 100K people in the main baseline (blue lines), and the alternative baseline assumption (red dot lines) for people 50 years or older. Including annual CRC deaths (per 100K people), annual CRC progressions (per 100K people), total CRC (per 100K people), undiagnosed CRC (per 100K people)

**Fig. S5.** Projected outcomes in the main baseline: comparison among the colonoscopy capacity, the availability of diagnostic colonoscopy for FIT positive, and FIT positive per year

**Fig. S6.** Projected outcomes in the alternative baseline assumption: comparison among the colonoscopy capacity, the availability of diagnostic colonoscopy for FIT positive, and FIT positive per year

### S7: Strategy analysis projection

In the strategy analysis, we aimed to compare strategies in current colonoscopy (200K people/year) and sufficient colonoscopy capacity (681K people/year). To calculate the sufficient colonoscopy that can satisfy all strategies, we first performed the analysis on an extremely high colonoscopy capacity (e.g., 50 times of the current capacity). Estimated colonoscopy demand from each strategy was present below. From Fig. S7, maximum colonoscopy demand from the baseline and

three strategies during 2023-2032 is 681K people. Thus, we concluded that sufficient colonoscopy capacity is 681K people/year.

**Fig. S7.** Colonoscopy demand in 10M people/year colonoscopy capacity

We gathered the target value of accessibility to FIT, and diagnostic colonoscopy from literature. We estimated the target value of AS (relative to the baseline) using the formulation below. Denote mean sojourn time (MST), transition rate between undiagnosed to diagnosed CRC by symptom (TRA), symptomatic detection rate (SDR). For CRC stage 1-4,

$$ASR_{target\ value} = \frac{AS_{target\ value}}{AS_{baseline}} = \frac{SDR\ CRC\ stage\ X_{target\ value}}{SDR\ CRC\ stage\ X_{baseline}}$$

Thus,

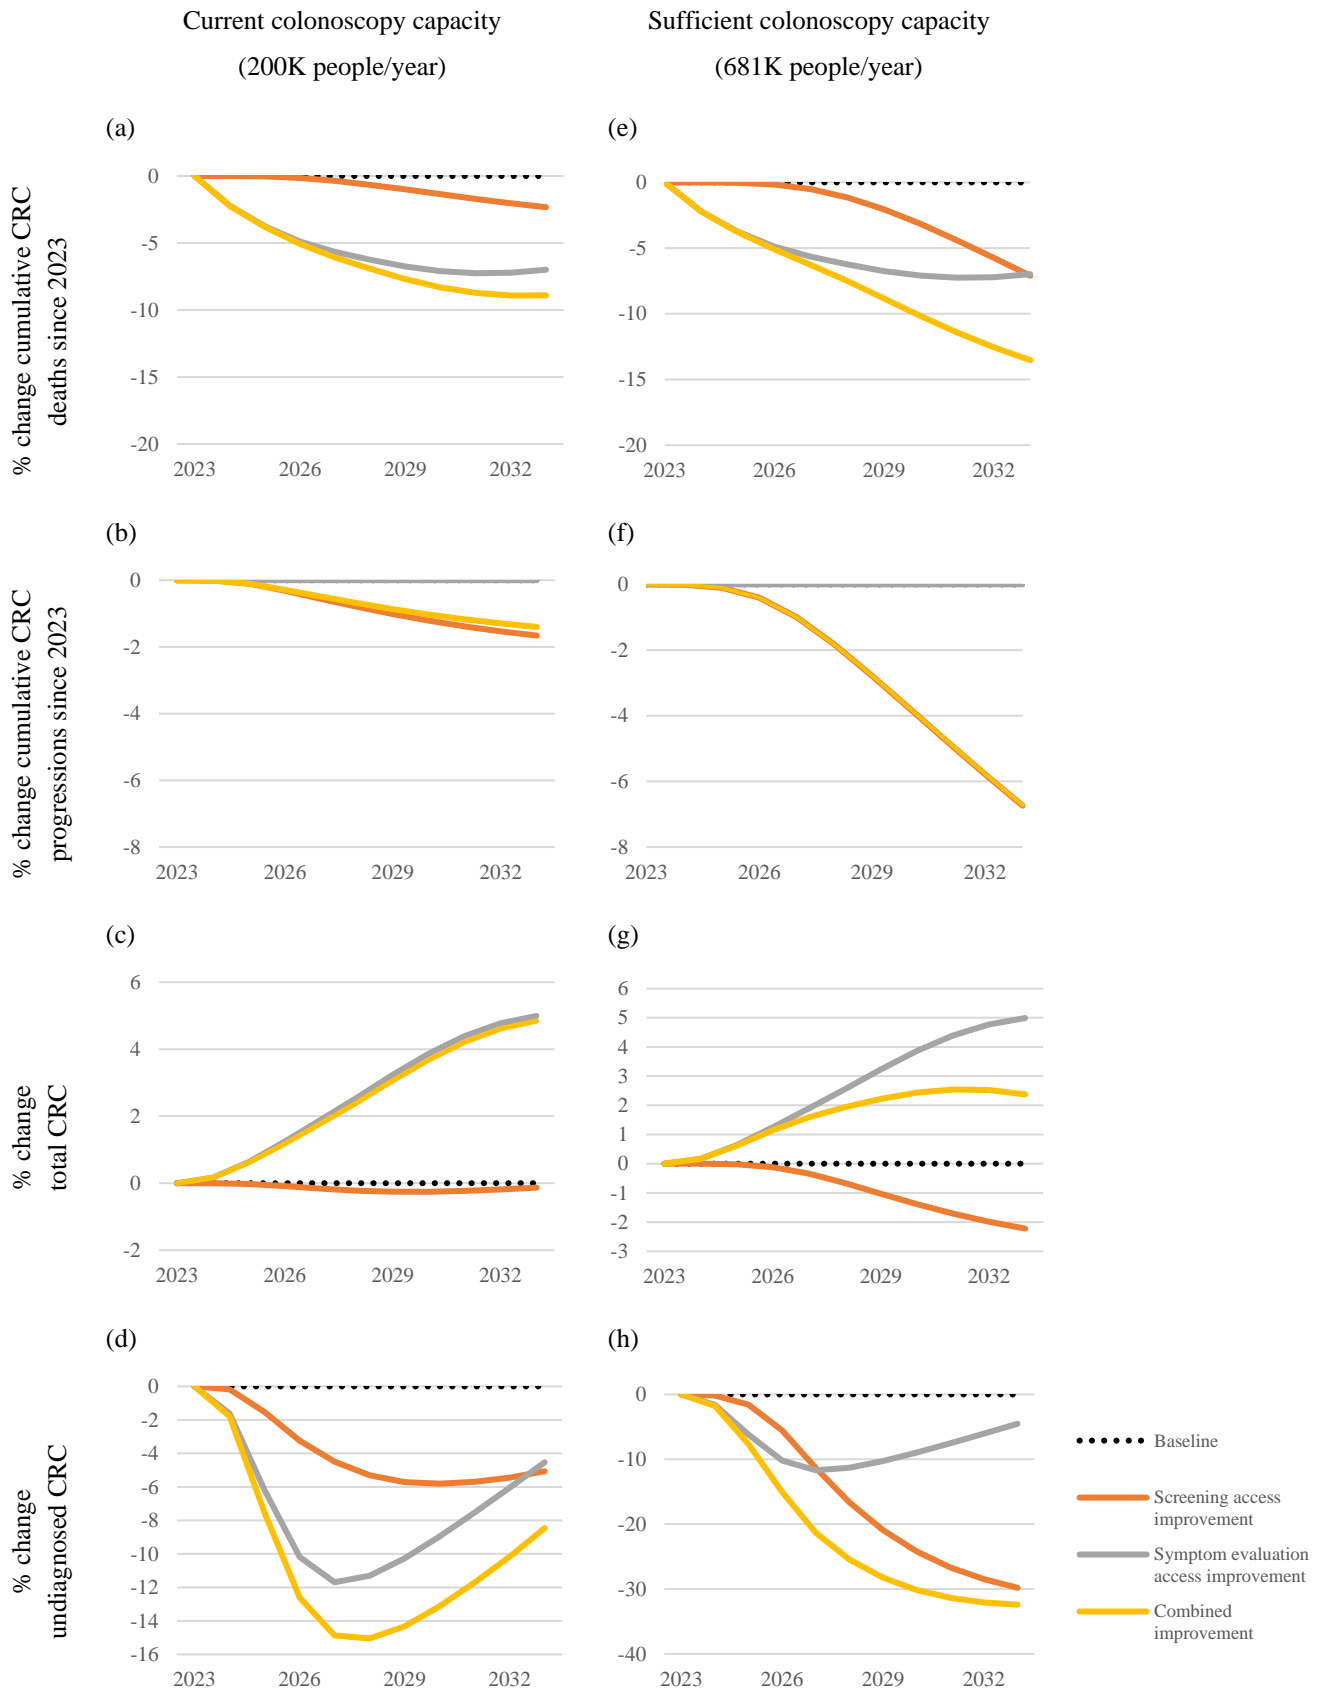

$$SDR\ CRC\ stage\ X_{target\ value} = ASR_{target\ value} * SDR\ CRC\ stage\ X_{baseline}$$

$$SDR\ CRC\ stage\ X = \frac{CRC\ stage\ X\ diagnosed\ by\ symptom\ per\ year}{Undiagnosed\ CRC\ stage\ X}$$

The literature shows the formulation of mean sojourn time below [32].

$$MST = \frac{1}{TRA} = \frac{\sum_{X=I}^{IV} CRC\ stage\ X\ diagnosed\ by\ symptom\ per\ year}{\sum_{X=I}^{IV} Undiagnosed\ CRC\ stage\ X}$$

we estimated  $ASRB_{target\ value} = 343\%$ , resulting in a mean sojourn time of 5 years in 2032 (the levels equal to the USA in 1997-2010). In other words, accessibility to symptom evaluation in Thailand is 29% of the level in the USA.

**Fig. S8.** Simulated outcomes' trajectories from each strategy compared to alternative baseline assumption, under current and sufficient colonoscopy capacities. % change cumulative CRC deaths since 2023 (a, e), % change cumulative CRC progressions since 2023 (b, f), % change total CRC (c, g), and % change of undiagnosed CRC (d, h)

## S8: Sensitivity analysis

**Fig. S9.** Projected changes in total CRC based on various levels of ‘Strategy-I: screening access improvement’ and ‘Strategy-II: symptom evaluation access improvement.’  
 AF: accessibility to FIT; AD: accessibility to diagnostic colonoscopy; ASR: accessibility to symptom evaluation relative to the baseline

**Fig. S10.** Projected changes in undiagnosed CRC based on various levels of ‘Strategy-I: screening access improvement’ and ‘Strategy-II: symptom evaluation access improvement.’  
 AF: accessibility to FIT; AD: accessibility to diagnostic colonoscopy; ASR: accessibility to symptom evaluation relative to the baseline

We performed one-way sensitivity analysis on model parameters with  $\pm 20\%$  range in uniform distribution. Fig. S11-Fig. S14 are tornado diagrams representing uncertainty from each parameter on primary outcomes (i.e., annual CRC deaths, annual CRC progressions) and secondary outcomes (i.e., total CRC, undiagnosed CRC), respectively. We reported all outcomes per cohort of 100K people

### Annual CRC deaths

**Fig. S11.** One-way sensitivity analysis represented annual CRC deaths per 100K people in baseline projections (baseline value: 115 people) over ten years

## Annual CRC progressions

**Fig. S12.** One-way sensitivity analysis represented annual CRC progressions per 100K people in baseline projections (baseline value: 160 people) over ten years

**Fig. S13.** One-way sensitivity analysis represented total CRC per 100K people in baseline projections (baseline value: 1,198 people) over ten years

## Undiagnosed CRC

**Fig. S14.** One-way sensitivity analysis represented undiagnosed CRC per 100K people in baseline projections (baseline value: 783 people) over ten years
