System Dynamics Modelling with Kotlin:
From Hierarchical Models to Interactive Simulators

Keywords: system dynamics, kotlin, modelling, complex system, hierarchical model, simulator

Funding Source/Alternate Affiliations: This work has been supported in part by Croatian Science
Foundation under the project UIP-2017-05-9066.

Extended Abstract: System dynamics (SD) modelling is traditionally done by graphically using
mostly proprietary software or with couple of open and free software exceptions. Building large
hierarchical models with reusable SD modules is not supported well and building fast and customizable
simulators for interactive learning on multiple target platforms is not trivial.

There are couple of framework/toolkit solutions that fulfill that gap using general-purpose languages
(Java, Python, JavaScript) but they have their own limitations. We asked whether Kotlin, as a new,
modern, statically-typed, null-safe, object-oriented and functional language can do any better and
overcome limitations of other programming languages and frameworks/toolkits. Therefore, we started
to develop Kotlin SD Toolkit which does not exist so far at our best knowledge.

We found that Kotlin as a new, programming language and our Kotlin SD Toolkit as a new tool are
both suitable for modelling larger, hierarchical SD models that support modules (see Table 1) and for
easier development of interactive simulators for multiple target platforms: desktop, web or mobile (see
Figures 1, 2 and 3).

We also measured speed properties without any a priori code optimizations and for now Kotlin SD
Toolkit on our computer needs 7 seconds to numerically integrate simple testing SD model with 1E7
time steps, which is very fast in comparison with others and can be additionally improved.

We will continue to further expand capabilities of the Kotlin SD Toolkit as an open source project and
our contribution to SD community.

<thead>
<tr>
<th>Steps</th>
<th>Kotlin code</th>
</tr>
</thead>
</table>
| 0) Setup   | ```java<br/>
companion object {<br/>
    const val TOTAL_POPULATION_VALUE = 10000 // [customer]<br/>
    const val ADVERTISING_EFFECTIVENESS_VALUE = 0.011 // [1/year]<br/>
    const val CONTACT_RATE_VALUE = 100 // [1/year]<br/>
    const val ADOPTION_FRACTION_VALUE = 0.015 // []<br/>
    const val INITIAL_TIME_VALUE = 0 // [year]<br/>
    const val FINAL_TIME_VALUE = 10 // [year]<br/>
    const val TIME_STEP_VALUE = 0.25 // [year]<br/>
}<br/>
1) Model    | ```java<br/>
init {<br/>
    val model = Model()<br/>
    // Override default model properties<br/>
    model.initialTime = INITIAL_TIME_VALUE<br/>
    model.finalTime = FINAL_TIME_VALUE<br/>
    model.timeStep = TIME_STEP_VALUE<br/>
    model.integration = EulerIntegration()<br/>
    model.name = "Innovation/Product Diffusion Model" // optional<br/>
2) Entities | ```java<br/>
- Constants<br/>
    val TOTAL_POPULATION = model.constant("TOTAL_POPULATION")<br/>
    val ADVERTISING_EFFECTIVENESS =<br/>
        model.constant("ADVERTISING_EFFECTIVENESS")<br/>
    val CONTACT_RATE = model.constant("CONTACT_RATE")<br/>
    val ADOPTION_FRACTION = model.constant("ADOPTION_FRACTION")<br/>
- Converters<br/>
    val adoptionFromAdvertising =<br/>
        model.converter("adoptionFromAdvertising")<br/>
    val adoptionFromWordOfMouth =<br/>
        model.converter("adoptionFromWordOfMouth")<br/>
- Stocks<br/>
    val Potential_Adopters = model.stock("Potential_Adopters")<br/>
    val Adopters = model.stock("Adopters")<br/>
- Flows<br/>
    val adoptionRate = model.flow("adoptionRate")<br/>
- Modules<br/>
3) Initial values | ```java<br/>
- Stocks<br/>
    Potential_Adopters.initialValue = { TOTAL_POPULATION }<br/>
    Adopters.initialValue = { 0.0 }<br/>
4) Equations  | ```java<br/>
- Constants<br/>
    TOTAL_POPULATION.equation = { TOTAL_POPULATION_VALUE }<br/>
    ADVERTISING_EFFECTIVENESS.equation =<br/>
        { ADVERTISING_EFFECTIVENESS_VALUE }<br/>
    CONTACT_RATE.equation = { CONTACT_RATE_VALUE }<br/>
    ADOPTION_FRACTION.equation = { ADOPTION_FRACTION_VALUE }<br/>
- Converters<br/>
    adoptionFromAdvertising.equation =<br/>
        { Potential_Adopters * ADVERTISING_EFFECTIVENESS }
adoptionFromWordOfMouth.equation =
  { CONTACT_RATE * ADOPTION_FRACTION * 
    Potential_Adopters * Adopters / TOTAL_POPULATION }

- Stocks
  Potential_Adopters.equation = { - adoptionRate }
  Adopters.equation = { adoptionRate }

- Flows
  adoptionRate.equation =
    { adoptionFromAdvertising + adoptionFromWordOfMouth }

- Modules

5) Simulation
  val simulation = Simulation(model)

6) Outputs
  simulation.outputs {
    - Text
      CsvExporter("output.csv", ",")
    - Image
      PngExporter("chart.png")
    - Desktop
      WinSimulator()
    - Web
      WebSimulator()
    - Mobile
      MobSimulator()
  }

7) Run
  simulation.run()
Figure 2. Web Simulator – an interactive simulation environment of the Bass diffusion model. The interactive simulation environment is a web application rendered in any Internet browser and is automatically generated based on entities’ type. We can change model constants, simulation settings and display the model diagram as an option.

Figure 3. Mobile Simulator – automatically generated interactive simulation environment for Bass diffusion model. The interactive simulation environment is an Android mobile application. We can change model constants and re-run the simulation on a mobile phone.
